

Model or Platform Used

I used Visual Studio Code with an AI coding assistant (GitHub Copilot / Claude / ChatGPT) to create my website. AI generated code based on my input to create the initial HTML, CSS, and JavaScript. I used VS Code's Live Server extension to test my changes and GitHub Pages to publish the website online.

Current Website Structure

The website has only one page with a fixed navigation bar. The current structure contains six sections: About Me, Education, Skills and Interests, Projects, Contact, and footer. Skills and Interests use cards and progress bars to highlight supply chain, entrepreneurship, and technologies knowledge. Projects contains five cards that can be filtered using special buttons. In Contact section you can find my email address, my location, and contact form.

Vibe Coding Process

I asked Copilot to create me a personal website with dark green and cream palette. The first draft contained a lot of placeholder text and had a bad mobile version. I worked on it using follow-up prompts to add a timeline, project filters, dark mode, and language switcher. With every step I was testing how it works and removing any private information that Copilot tried to add.

What I Learned

The most valuable thing that I have learned in the process is that it takes some time for humans to check what the AI writes. Copilot generated a lot of new facts about me that I had to correct. Also, Copilot's first mobile version contained a layout that was overflowing the screen at some point. I learned that I have to use CSS media queries and flexible grid layouts to fix that. One of unexpected challenges was that I had to fix my language switcher because Chinese characters were taking more space than English letters.

Future Plans

I would add a working contact form, expand project pages, add a learning blog, increase accessibility, and create a button to download my resume. Also, I would expand my Projects section with detailed pages with pictures, case description, and a downloadable PDF file.
